UNIVERSITY INSTITUTE of COMPUTING
Asia's Fastest Growing University

NAAC GRADE A+ ACCREDITED UNIVERSITY

Worksheet 3

Student Name: Sahil Sharma **UID:** 26MCI10257

Branch: MCA (AI & ML) **Section/Group:** 26MAM-4B

Semester: 1st **Date of Performance:** 01/09/2026

Subject: Python Programming (LAB) **Subject Code:** 26CAH-606

EXPERIMENT:

Implement a Student class with information such as roll number, name, and class. The information must be entered by the user.

AIM:

To create a Student class in Python, accept student information from the user, store the information using an object, and display the entered student details.

OBJECTIVE:

The objective of this experiment is to understand and implement **classes and objects in Python**. The experiment aims to create a **Student class** with attributes such as roll number, name, and class, accept student information from the user, store it in an object, and display the entered student details.

THEORY:

- **Class:** A class is a blueprint or template used to create objects. It contains data and functions related to an entity.
- **Object:** An object is an instance of a class. It is used to access the data and methods defined inside the class.
- **Constructor:** The __init__() method is a special method that runs automatically when an object is created.
- **self:** The self parameter refers to the current object and is used to access its variables and methods.

- **Instance Variables:** rollno, name, and student_class are instance variables because their values belong to a particular Student object.
- **Method:** display_details() is a method used to display the information stored in the Student object.
- **User Input:** The input() function is used to take the student's roll number, name, and class from the user.

CODE :

```
class Student:
    def __init__(self, roll_number, name, student_class):
        self.roll_number = roll_number
        self.name = name
        self.student_class = student_class

    def display_details(self):
        print(f"Roll Number: {self.roll_number}")
        print(f"Name: {self.name}")
        print(f"Class: {self.student_class}")

# Accepting student information from the user
roll_number = input("Enter roll number: ")
name = input("Enter name: ")
student_class = input("Enter class: ")

# Creating a Student object
student = Student(roll_number, name, student_class)

# Displaying the student details
student.display_details()
```

OUTPUT:

```
PS C:\Users\Sahilll17> python -u "C:\Users\SAHILL~1\AppData\Local\Temp\tempCodeRunnerFile.python"
Enter roll number: 26MCI10257
Enter name: Sahil Sharma
Enter class: MAM-4B
Roll Number: 26MCI10257
Name: Sahil Sharma
Class: MAM-4B
PS C:\Users\Sahilll17>
```

LEARNING OUTCOMES:

- Understand the concept of classes and objects in Python.
- Create a user-defined class using the class keyword.
- Understand the purpose of the __init__() constructor.
- Use self to access instance variables and methods.
- Accept object information dynamically using input().
- Create an object and call its method.
- Store and display student information using object-oriented programming.
